

# JavaScript Basics

## What is JavaScript?

From Wikipedia:

... high-level, dynamic, untyped, and interpreted programming language

... is prototype-based with first-class functions, ...

... supporting object-oriented, imperative, and functional programming

... has an API for working with text, arrays, dates and regular expressions

- Not particularly similar to Java: More like C crossed with Self/Scheme
  - C-like statements with everything objects, closures, garbage collection, etc.
- Also known as ECMAScript

### Some thoughts about JavaScript

- Example of a scripting language
  - Interpreted, less declaring of things, just use them (popular today: e.g. python)

- Seems like it was designed in a rush
  - Some "Good Parts", some not so good
  - Got a bad reputation

- Many programmers use a subset that avoids some common problems
- "use strict"; tweaks language to avoid some problematic parts
- Language being extended to enhance things: New ECMAScript every year!
  - Transpiling common so new features used: e.g ECMAScript Version N, TypeScript
- Code quality checkers (e.g. jslint, jshint, eslint) widely used

## Good news if you know C - JavaScript is similar

```
Be Practical®
TECH SOLUTIONS
```

```
/ 10);
while (i >= 0) {
   sum += i*i; // Comment
   i--;
for (i = 0; i < 10; i++)
/* this is a comment */
```

```
if (i < 3) {
    i = foobar(i);
} else { i = i
    * .02;
}</pre>
```

Most C operators work:

```
Be Practical®
TECH SOLUTIONS
```

```
* / % + - ! >= <= > < && || return i;}
?: function foobar(i) { continue/break/return</pre>
```

### JavaScript has dynamic typing

```
var i;  // Need to define variable ('use strict';), note: untyped
typeof i == 'undefined' // It does have a type of 'undefined' i =
32;  // Now: typeof i == typeof 32 == 'number' i = "foobar"; //
```

```
Be Practical®
TECH SOLUTIONS
```

```
Now: typeof i == typeof 'foobar' == 'string' i = true; // Now typeof i == 'boolean'
```

- Variables have the type of the last thing assigned to it
- Primitive types: undefined, number, string, boolean, function, object

### Variable scoping with var: Lexical/static scoping

```
Two scopes: Global and function local All var statements hoisted to top of scope:
```

```
var globalVar; function foo() {
```

```
function foo() {
  var localVar;
  if (globalVar > 0) {
    var localVar2 = 2;
  }
  // localVar2 is valid here
}
```

```
var x;
x = 2;
// Same as:
function foo() {
    x = 2
    var x;
```

localVar2 is
hoisted here but
has value undefined

### Var scope problems

- Global variables are bad in browsers Easy to get conflicts between modules
- Hoisting can cause confusion in local scopes (e.g. access before value set) function() { console.log('Val is:', val); ... for(vari = 0; i < 10; i++) { var val = "different string"; // Hoisted to func start</p>
- Some JavaScript guides suggest always declaring all var at function start
- ES6 introduced non-hoisting, scoped let and const with explicit scopes
   Some coding environments ban var and use let or const instead

### Var scope problems

- Global variables are bad in browsers Easy to get conflicts between modules
- Hoisting can cause confusion in local scopes (e.g. access before value set) function() { console.log('Val is:', val); // Syntax error
   ... for(leti = 0; i < 10; i++) {</li>
   let val = "different string"; // Works
- Some JavaScript guides suggest always declaring all var at function start
- ES6 introduced non-hoisting, scoped **let** and explicit scopes

### Some coding environments ban var and use let or const instead

### number type

number type is stored in floating point (i.e. double in C)

$$MAX_INT = (2^{53} - 1) = 9007199254740991$$

Some oddities: NaN, Infinity are numbers

Nerd joke: typeof NaN returns 'number'

### string type

string type is variable length (no char type)

```
let foo = 'This is a test'; // can use "This is a test"
foo.length // 14
```

```
+ is string concat operator
    foo = foo + 'XXX'; // This is a testXXX

Lots of useful methods: indexOf(), charAt(), match(), search(),
replace(), toUpperCase(), toLowerCase(), slice(), substr(), ...
    'foo'.toUpperCase() // 'FOO'
```

### boolean type

• Either true or false

- Language classifies values as either truthy or falsy Used when a value is converted to a boolean e.g. if (foo) { ... )
- Falsy: false, 0, NaN, "", undefined, and null ●

Truthy:

Not falsy (all objects, non-empty strings, non-zero/NaN numbers, functions, etc.)

### undefined and null

undefined - does not have a value assign

```
let x; // x has a value of undefined x =
undefined; // It can be explicitly store
typeof x == 'undefined'
```

null - a value that represents whatever the user wants it to

```
Use to return special condition (e.g. no value) typeof null == 'object'
```

Both are falsy but not equal (null == undefined; null !== undefined)

### function type

```
function foobar(x) {    if (x <= 1) {
return 1;    }    return x*foobar(x-1); }    typeof
foobar == 'function'; foobar.name == 'foobar'</pre>
```

- Function definitions are hoisted (i.e. can use before definition)
- Can be called with a different number arguments than definition
  - Array arguments variable (e.g. arguments[0] is first argument)
  - Unspecified arguments have value undefined

All functions return a value (default is undefined)

# "First class" function example

#### retVal 11

### 

Func called with 10

### object type

- Object is an unordered collection of name-value pairs called **properties** let foo = {}; let bar = {name: "Alice", age: 23, state: "California"};
   Name can be any string: let x = { "": "empty", "---": "dashes"}
- Referenced either like a structure or like a hash table with string keys:

```
bar.name or bar["name"]
x["---"]  // have to use hash format for illegal names
foo.nonExistent == undefined
```

Global scope is an object in browser (i.e. window[prop])

### Properties can be added, removed, enumerated

To add, just assign to the property:

```
let foo = {};
foo.name = "Fred";  // foo.name returns "Fred"
```

• To remove use delete:

```
let foo = {name: "Fred"};
delete foo.name; // foo is now an empty object
```

• To enumerate use Object.keys():

```
Object.keys({name: "Alice", age: 23}) = ["name", "age"]
```

### Arrays

```
let anArr = [1,2,3];
```

Are special objects: typeof anArr == 'object'

Indexed by non-negative integers: (anArr[0] == 1)

Can be **sparse** and **polymorphic**: anArr[5]='FooBar'; //[1,2,3,,,'FooBar']

Like strings, have many methods: anArr.length == 3 push, pop, shift, unshift, sort, reverse, splice, ...

Oddity: can store properties like objects (e.g. anArr.name = 'Foo') Some properties have implications: (e.g. anArr.length = 0;)

### **Dates**

```
let date = new Date();
```

Are special objects: typeof date == 'object'

The number of milliseconds since midnight January 1, 1970 UTC

Timezone needed to convert. Not good for fixed dates (e.g. birthdays)

Many methods for returning and setting the data object. For example:
 date.valueOf() = 1452359316314 date.toISOString() =
 '2016-01-09T17:08:36.314Z' date.toLocaleString() =
 '1/9/2016, 9:08:36 AM'

### Regular Expressions

```
let re = /ab+c/; or let re2 = new RegExp("ab+c");
```

Defines a pattern that can be searched for in a string

```
String: search(), match(), replace(), and split()
RegExp: exec() and test()
```

Cool combination of CS Theory and Practice: CS143

#### Uses:

Searching: Does this string have a pattern I'm interested in?

Parsing: Interpret this string as a program and return its components

# Regular Expressions by example - search/test

```
/HALT/.test(str); // Returns true if string str has the substr HALT
/halt/i.test(str); // Same but ignore case
/[Hh]alt [A-Z]/.test(str); // Returns true if str either "Halt L" or "halt L"
```

```
'XXX abbbbbbc'.search(/ab+c/); // Returns 4 (position of 'a')
'XXX ac'.search(/ab+c/); // Returns -1, no match
'XXX ac'.search(/ab*c/); // Returns 4
'12e34'.search(/[^\d]/); // Returns 2
'foo: bar;'.search(/...\s*:\s*...\s*;/); // Returns 0
```

# Regular Expressions - exec/match/replace

```
let str = "This has 'quoted' words like 'this'";
let re = /'[^']*'/g;
```

### Exceptions - try/catch

 Error reporting frequently done with exceptions Example: nonExistentFunction();

Terminates execution with error:

Uncaught ReferenceError: nonExistentFunction is not defined

```
    Exception go up stack: Catch exceptions with try/catch try
        { nonExistentFunction(); } catch (err) { //
        typeof err 'object' console.log("Error call func",
        err.name, err.message);
    }
```

### Exceptions - throw/finally

Raise exceptions with throw statement try {
 throw "Help!";

```
} catch (errstr) { // errstr === "Help!"
console.log('Got exception', errstr);
} finally {
    // This block is executed after try/catch
}
```

 Conventions are to throw sub-classes of Error object console.log("Got Error:", err.stack || err.message || err);

## Getting JavaScript into a web page

By including a separate file:

```
<script type="text/javascript" src="code.js"></script>
```

• Inline in the HTML:

```
<script type="text/javascript">
//<![CDATA[ Javascript
goes here...
//]]>
```

</script>
